INTRODUCTION

An AI job recommendation system will be developed for the IT industry to connect suitable employers and job seekers. The system will use AIDA advertising, Personalized PageRank algorithm and web/mobile apps to optimize job search and connections.

OBJECTIVES

- Define suitable advertising model for recruitment - AIDA
- Develop web and mobile app for job seeking
- Build AI recommender system to help employers and candidates find each other
- Provide features to attract more users

CHALLENGES

- Recruitment data is scarce, hard to collect like job description, employer data. These datasets important for training models.
- Evaluating recommender model is difficult as output changes over time.
- Choosing ad model is time-intensive.

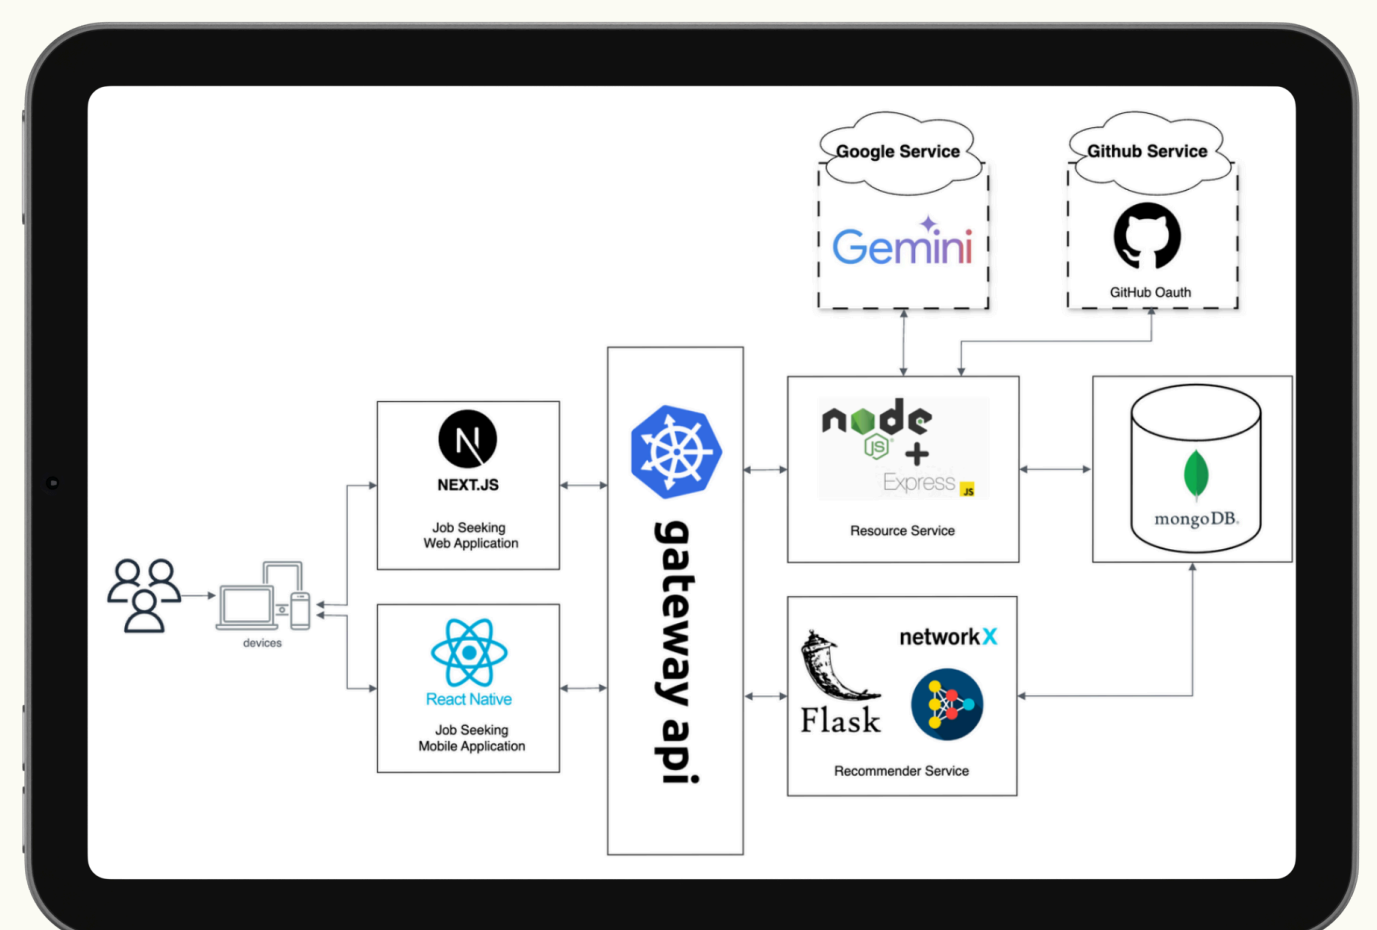

RESEARCH METHOD

- Generate features following the AIDA strategy
- Establish a forum for employers and candidates
- Create a chatbot for answering recruitment inquiries
- Construct a graph-based recommender system with the following components:
 - Represent resumes, jobs, and employers as nodes in a vectorized format
 - Visualize the relationships between three nodes (employer, candidate, job) using PageRank and LSA in a graph network
 - Determine candidate-job similarity using Cosine Similarity
 - Recommend suitable jobs to candidates

ARCHITECTURE

Users access via mobile/browser apps
Apps interact with servers through API gateway
Two server types: recommender, resource management
Third party services: Github OAuth for auth, Gemini for analysis
Data stored in MongoDB for diverse structures (resumes, jobs, etc)

CONCLUSION

We created AI modules for the AIDA advertising model, including CV creation, job email subscriptions, etc. We also developed a job recommendation system using graphs and PageRank for an online advertising demo. In the future, we plan to work on mobile apps, system scaling, security enhancements, and further AI integration.
